

Phase 1 of 4

Foundation — Authentication, Landing Page & Core Dashboards

Maternal Health Platform — Development Roadmap · Derived strictly from the Patient, Doctor, and Hospital User Flow documents

NOTE : KEEP ONLY 3 PROFILES DO NOT INCLUDE OTHERS

What This Phase Covers

This phase builds the entry point of the platform and the identity layer for all four user types: Maternal Patient, Doctor, Hospital, and General User. Nothing here depends on vitals, the LLM, or hospital-doctor-patient mapping — those are built in later phases. By the end of this phase every user type can register, log in, and land on their own dashboard shell.

1. The Landing Page — Four Profile Options

When any user opens the application for the first time, they see a landing page with four clearly labelled profile options:

- Maternal Patient — for pregnant women using the platform for pregnancy monitoring and guidance
- Doctor — for gynecologists and other doctors monitoring their patients
- Hospital — for hospital organisations registering and managing their doctors and patients
- Other / General User — for anyone using the platform without a specific medical context

NOTE: A maternal patient and a general user follow the same authentication and dashboard flow. The only difference between them is LLM behaviour (covered in Phase 4). Both get hospital browsing, wearable monitoring, and vitals tracking.

2. Patient Registration and Login

Step 1 — First-Time Registration

A new patient creates her own account independently. No hospital involvement is needed at this step.

Registration fields:

- Email address — used as the primary login identifier
- Password — chosen by the patient
- OTP verification — one-time password sent to her email to confirm it

After OTP verification the account is created and she lands directly on her dashboard. This registration happens only once.

Step 2 — Returning Patient — Direct Login

On every visit after the first, the patient enters only her email and password. No OTP, no re-verification, no re-registration. The platform remembers her session on most devices — she only re-enters credentials if she explicitly logs out or changes device.

3. Doctor Registration and Login

Step 1 — First-Time Registration — Personal Account Only

A doctor registers using his own personal identity, never a hospital-issued credential. Hospital-issued credentials are only ever used later (Phase 2 of this roadmap) to unlock a specific hospital's patient list — they are never entered at this personal registration screen.

Registration fields:

- Personal email address — his own, not a hospital-provided one
- Password — chosen by the doctor himself
- OTP verification — sent to his personal email

Step 2 — Returning Doctor — Direct Login

Every subsequent visit uses just personal email and password. No OTP, no re-verification.

Edge Cases — Doctor Registration

Edge Case	What Happens
Doctor tries to register with an email already registered	Blocked with: "This email is already registered. Please login instead."
Doctor mistakenly enters hospital-issued credentials at this personal registration screen	System does not recognise hospital credentials here. Registration proceeds only with a genuine personal email.
OTP not received or expires	"Resend OTP" available; new OTP valid for 10 minutes, up to 3 resend attempts.
Doctor forgets his personal password	"Forgot Password" resets it via his personal email — has no effect on any hospital-issued credentials held separately.

4. Hospital Registration and Login

Step 1 — First-Time Registration

A hospital registers once with full credentials. All eight fields below are mandatory — registration cannot be submitted with any field empty, and the account is not created until the OTP is verified.

- Hospital name
- Email address — used as the primary login identifier
- Password — chosen by the hospital administrator
- OTP verification
- Address — full street/building address

- Pincode — 6-digit postal code
- Area — locality or neighbourhood
- District — the administrative district

Once the OTP is confirmed, the account is created and the admin lands directly on the Hospital Management Dashboard.

Step 2 — Returning Hospital — Direct Login

Every visit after the first is a direct login with email and password. No OTP, no re-entry of address/pincode.

Edge Cases — Hospital Registration

Edge Case	What Happens
Hospital enters an already-registered email	Blocked with: "This hospital is already registered. Please login instead."
OTP not received or expires before entry	"Resend OTP" option; new OTP valid 10 minutes; up to 3 resend attempts before form restarts.
Pincode entered is not a valid 6-digit number	Inline validation error shown immediately; submission blocked until corrected.
Hospital forgets its password	"Forgot Password" sends a reset OTP; has no effect on any doctor's or patient's own credentials.
A hospital chain registers multiple branches at the same address	Allowed — each branch is a fully independent account with its own doctors, patients, and access codes. Branches are never automatically linked.

5. Patient's Two Main Dashboards (Shells Only in This Phase)

After login, the patient sees two clearly separated, completely independent dashboards. She can use one without the other:

Dashboard 1 — LLM Dashboard (Lifestyle Companion)

A private AI chat interface available to all users. Its full behaviour (diet, exercise, emotional support, report explanation, etc.) is built out entirely in Phase 4 of this roadmap. In this phase, only the dashboard shell and navigation entry point need to exist.

Dashboard 2 — Hospital Management Dashboard (Clinical Hub)

Contains three sections, always visible:

- My Wearable Device — connect/disconnect simulation, view live vitals (built in Phase 3)
- My Connected Hospitals — connected hospitals, doctors, reports, appointments, chat, prescriptions (built in Phase 2)
- All Registered Hospitals — browse and view any hospital publicly (built in Phase 2)

NOTE: Connecting to a hospital and connecting the wearable device are two completely separate actions in this platform. Neither triggers the other. Keep this separation in mind while designing the dashboard shell now, even though both features are implemented in later phases.

6. Doctor Dashboard Overview (Shell Only in This Phase)

After login, the doctor sees one single dashboard — there is no split between an LLM area and a management area the way there is for a patient. The centrepiece is a search bar listing every hospital registered on the platform.

- Search Hospitals — the public directory, open to browse freely
- My Unlocked Hospitals — hospitals where he has entered hospital-issued credentials and can see patients (empty until the unlock flow, built in Phase 2, is completed at least once)

Edge Case

Doctor has never unlocked any hospital: he can still use the search bar and browse every public hospital directory indefinitely. "My Unlocked Hospitals" simply shows "No hospitals unlocked yet."

7. Hospital Dashboard Overview (Shell Only in This Phase)

Unlike the patient, the hospital sees only one dashboard. There is no LLM chat on the hospital side — the AI assistant is a patient-only feature. The dashboard is organised into the following sections, always visible:

- My Doctors — view, add, edit, or deactivate doctors registered under this hospital (built out in Phase 2)
- My Patients — view every patient mapped across all doctors, filterable by doctor (built out in Phase 2)
- Register New Doctor — add a new doctor's full credentials (built out in Phase 2)
- Register New Patient / Generate Access Code — map a patient to a doctor and issue her connection code (built out in Phase 2)
- Hospital Public Profile — the editable information every patient sees when browsing hospitals
- Notifications — hospital-side alerts (built out in Phase 4)

NOTE: The Hospital Public Profile is exactly the information a patient sees when she searches for this hospital from her own dashboard — name, address, area, district, pincode, and doctor list. There is no separate copy; both sides read the same record.

Edge Case

Hospital has zero doctors registered yet: it still appears in public search with its name and address. The doctor list section shows "No doctors registered yet" instead of an empty table.

8. Design Principles Established in This Phase

These rules recur throughout every later phase, so they must be built correctly here:

- One-time personal registration with OTP, direct login every time after — identical pattern for patient, doctor, and hospital.
- A hospital-issued credential (for doctors) acts purely as a one-time unlock key, never as a second account.
- Deactivate, never hard-delete, whenever medical or audit history could exist.
- Per-hospital isolation is a platform-wide principle — it governs doctor and patient data everywhere from Phase 2 onward.

Phase 1 Summary Table

Component	Key Rule Established
Landing page	Four profile types: Patient, Doctor, Hospital, General User.
Patient auth	Email + password + OTP once; direct login after.
Doctor auth	Personal email only at registration; hospital credentials are never used here.
Hospital auth	8 mandatory fields + OTP once; direct login after.
Patient dashboards	Two independent shells: LLM Dashboard and Hospital Management Dashboard.
Doctor dashboard	One dashboard centred on a public hospital search bar.
Hospital dashboard	One management hub; no LLM chat on the hospital side.
